

# MATH 612 FINAL PROJECT

HIDENORI SHINOHARA

ABSTRACT. This is based on the book *4-Manifolds and Kirby Calculus* by Robert E. Gompf and Andras I. Stipsicz. We will start by defining manifolds and tangent bundles, and introduce the cup product as a tool to work with 4-manifolds.

## CONTENTS

1. Manifolds	1
2. Homology	3
3. Complex Structure	3
4. Cohomology	4
5. 4-manifolds	4

## 1. MANIFOLDS

**Definition 1.1.** A topological manifold is a separable Hausdorff space such that every point has a neighborhood which is homeomorphic to an open subset of  $\mathbb{R}_+^n$ . Each pair  $(U_\alpha, \phi_\alpha)$  containing a neighborhood and a homeomorphism is called a chart, and a collection of charts covering the manifold is called an atlas of the manifold.

**Definition 1.2.** A topological manifold is called a  $C^r$ -manifold if, for every pair of charts in the given atlas, the transition function  $\phi_\alpha \circ \phi_\beta^{-1}$  is  $C^r$ .

This definition makes sense because  $\phi_\alpha \circ \phi_\beta^{-1}$  maps  $U_\beta$  into  $U_\alpha$ , both of which are open subsets of  $\mathbb{R}_+^n$ , thus the usual calculus definition of  $C^r$  is applied. More rigorously, a  $C^r$ -manifold is  $(X, \mathcal{T}, \mathcal{A})$  where  $X$  is the set,  $\mathcal{T}$  is the set of open subsets of  $X$ , and  $\mathcal{A}$  is the atlas of  $X$ . However, just like we normally say a topological space  $X$  instead of  $(X, \mathcal{T})$ , we normally just say a  $C^r$ -manifold  $X$  without specifying the atlas.

**Definition 1.3.** Let  $X, X'$  be  $C^r$ -manifolds. Then a map  $f : X \rightarrow X'$  is called a  $C^r$ -map if  $\phi_\alpha \circ f \circ \phi_\beta^{-1}$  is  $C^r$  for  $\alpha, \beta$ . Moreover,  $f$  is called a  $C^r$ -diffeomorphism if  $f$  is bijective and both  $f$  and  $f^{-1}$  are  $C^r$ -maps.

Again, in this definition, the usual calculus definition of  $C^r$  is used for  $\phi_\alpha \circ f \circ \phi_\beta^{-1}$ .

**Definition 1.4.** Let  $X$  be a topological manifold. Let  $A, A'$  be two atlases of  $X$  such that  $(X, A)$  and  $(X, A')$  are both  $C^r$  manifolds. The two structures are called isotopic if the “identity” map  $(X, A) \mapsto (X, A')$  is isotopic to a  $C^r$ -diffeomorphism between  $(X, A)$  and  $(X, A')$ .

We will usually consider structures up to isotopy.

**Example 1.5.** TODO Examples of isotopic structures.

**Definition 1.6.** A compact manifold with no boundary is said to be closed.

**Definition 1.7.** A space  $X$  is said to be a singular manifold if the complement of a finite subset of  $X$  is a smooth manifold.

**Definition 1.8.** Let  $X$  be a smooth manifold. A derivation at  $p \in X$  is a linear map  $v : C^\infty(X) \rightarrow \mathbb{R}$  such that

$$v(fg) = f(p)vg + g(p)vf$$

for all  $f, g \in C^\infty(X)$ .

This corresponds to “arrows that are tangent to  $X$  and whose basepoints are attached to  $X$  at  $p$ ” even though it may not be easy to see that from this definition.

**Definition 1.9.** The tangent space  $T_p X$  to  $X$  at  $p$  is the vector space of all derivations of  $C^\infty(X)$  at  $p$ .

**Definition 1.10.** The tangent bundle  $TX$  is the disjoint union  $\coprod_{p \in X} T_p X$ .

Note that given the projection  $\pi : TX \rightarrow X$ ,  $\pi^{-1}(p)$  is a vector space isomorphic to  $\mathbb{R}^n$  where  $X$  is an  $n$ -dimensional manifold.

Next, we will define an orientation of a manifold using a tangent bundle.

**Definition 1.11.** Two ordered bases  $(E_1, \dots, E_n)$  and  $(\tilde{E}_1, \dots, \tilde{E}_n)$  for  $V$  are consistently oriented if the transition matrix  $(B_i^j)$ , defined by

$$E_i = B_i^j \tilde{E}_j$$

has positive determinant.

Since the transition matrix always has nonzero determinant, by fixing an ordered basis, we can split all ordered bases into two disjoint sets, one of which contains consistently oriented bases. This leads to the following definition:

**Definition 1.12.** A vector space with a choice of orientation is an oriented vector space.

**Definition 1.13.** The orientation  $[e_1, \dots, e_n]$  of  $\mathbb{R}^n$  determined by the standard basis is called the standard orientation.

This definition can be applied to a tangent space because, even though the definition of a tangent space may seem complicated, it is a vector space.

**Definition 1.14.**  $M, N$  are smooth manifolds with or without boundary, and  $F : M \rightarrow N$  is a smooth map. The differential of  $F$  at  $p$  is the linear map  $dF_p : T_p M \rightarrow T_{F(p)} N$  defined by

$$dF_p(v) := f \mapsto v(f \circ F)$$

Equivalently,  $\forall v \in T_p M, \forall f \in C^\infty(N), dF_p(v)(f) = v(f \circ F)$ . This corresponds to “the directional derivative of  $F$  at  $p$  in the direction of the arrow  $v$ .”

**Definition 1.15.** A consistent choice of orientation of the tangent space at each point of  $X$  is called an orientation of  $X$ . A choice is consistent if and only if for each point in  $X$ , there is a chart  $(V, \phi)$  mapping into  $\mathbb{R}^n$  with its standard orientation, such that  $d\phi_p$  preserves orientation at every point  $p$  of  $V$ .

**Definition 1.16.** A manifold is orientable if it admits an orientation and it is said to be oriented if an orientation of  $X$  is fixed.

## 2. HOMOLOGY

**Definition 2.1.** A continuous map  $\delta^n \rightarrow X$  is called a singular  $n$ -simplex.

**Definition 2.2.**  $C_n(X; R)$  is defined to be the abelian group generated by all singular  $n$ -simplices in  $X$  with coefficients in  $R$ .

**Definition 2.3.**  $C_n(X, A; R)$  is defined to be the quotient group  $C_n(X)/C_n(A)$  where  $A \subset X$ .

**Definition 2.4.** A boundary map  $\partial_n : C_n(X, A; R) \rightarrow C_{n-1}(X, A; R)$  is defined to be

$$\partial_n(\sigma) = \sum_i (-1)^i \sigma|_{[v_0, \dots, \hat{v}_i, \dots, v_n]}.$$

**Definition 2.5.** The relative homology group  $H_n(X, A; R)$  is defined to be  $\ker(\partial_n)/\text{Im}(\partial_{n+1})$ .

**Theorem 2.6.** An orientation as defined above specified a class  $[X]$  in  $H_n(X, \partial X; \mathbb{Z})$ , called the fundamental class of the oriented manifold.

## 3. COMPLEX STRUCTURE

**Definition 3.1.** A complex function is said to be holomorphic if it is differentiable at every point.

**Definition 3.2.** An atlas  $\{(U_\alpha, \phi_\alpha) | \alpha \in A_{\mathbb{C}}\}$  on a real  $2n$ -dimensional manifold  $X$  is a complex structure if each  $\phi_\alpha$  is a homeomorphism between  $U_\alpha$  and an open subset of  $\mathbb{C}^n$  which is identified with  $\mathbb{R}^{2n}$  and the transition functions  $\phi_\beta \circ \phi_\alpha^{-1}$  is holomorphic.

**Example 3.3.**  $X = \mathbb{R}^2$  is a 2-dimensional manifold. Let  $\phi_\alpha : (x, y) \mapsto (x, y)$  and  $\phi_\beta : (x, y) \mapsto (x, -y)$ .  $(X, \phi_\alpha), (X, \phi_\beta)$  are both smooth charts of  $X$  and they are compatible. However, if we identify  $\mathbb{R}^2$  with  $\mathbb{C}$ , the transition function  $\phi_\beta \circ \phi_\alpha^{-1}$  is exactly the complex conjugate function.

$$\begin{array}{ccc} \mathbb{R}^2 & \longleftrightarrow & \mathbb{C} \\ \phi_\alpha \uparrow & & \downarrow \phi_\beta \circ \phi_\alpha^{-1} \\ X & & \\ \downarrow \phi_\beta & & \\ \mathbb{R}^2 & \longleftrightarrow & \mathbb{C} \end{array}$$

From complex analysis, we know that the conjugate function is not holomorphic. Therefore, an atlas containing  $\phi_\alpha$  and  $\phi_\beta$  is not a complex structure. Of course, the atlas only containing  $(X, \phi_\alpha)$  is indeed a complex structure.

**Definition 3.4.** A smooth isotopy between embeddings  $\phi_0, \phi_1 : Y \rightarrow X$  is a smooth homotopy  $\phi_t : Y \rightarrow X$  through embeddings.  $\phi_0$  and  $\phi_1$  are said to be isotopic if an isotopy exists.

**Example 3.5.** Let  $X \subset \mathbb{R}^2$  be an open unit disk. Then the embedding  $\phi_0 : (x, y) \mapsto (x, y)$  and  $\phi_1 : (x, y) \mapsto (x, y + 1)$  is isotopic by the isotopy  $\phi_t : (x, y) \mapsto (x, y + t)$ .

**Theorem 3.6.** Suppose that  $X$  is a  $C^r$ -manifold and  $1 \leq r \leq k$ . Then there exists a  $C^k$ -atlas of  $X$  for which the induced  $C^r$  structure is isotopic to the original  $C^r$ -structure of  $X$ .

By this theorem (Theorem 1.1.6 in *4-Manifolds and Kirby Calculus*), classifying  $C^r$ -manifolds up to isotopy for any  $r < \infty$  is simply a subproblem of the classification problem for  $r = \infty$  because any given  $C^r$ -manifold for  $r \in \mathbb{N}$  can be given a unique (up to isotopy)  $C^\infty$  structure.

#### 4. COHOMOLOGY

**Definition 4.1.**  $C^n(X, A; R)$  is defined to be the dual group  $\text{Hom}(C_n(X, A), R)$ .

**Definition 4.2.** A coboundary map  $\delta : C^n(X, A; R) \rightarrow C^{n+1}(X, A; R)$  is defined to be

$$\delta\phi(\sigma) = \sum_i (-1)^i \phi(\sigma|_{[v_0, \dots, \hat{v}_i, \dots, v_{n+1}]}).$$

**Definition 4.3.** The relative cohomology group  $H^n(X, A; R)$  is defined to be  $\ker(\delta)/\text{Im}(\delta)$ .

**Definition 4.4.** For cochains  $\phi \in C^k(X; R)$  and  $\psi \in C^l(X; R)$ , the cup product  $\phi \smile \psi \in C^{k+l}(X; R)$  is the cochain whose value on a singular simplex  $\sigma : \Delta^{k+l} \rightarrow X$  is given by the formula

$$(\phi \smile \psi)(\sigma) = \phi(\sigma|_{[v_0, \dots, v_k]})\psi(\sigma|_{[v_k, \dots, v_{k+l}]})$$

where the right hand-side is the product in  $R$ .

By Lemma 3.6[Hatcher], we know that the cup product of two cocycles is a cocycle, and the cup product of a cocycle and a coboundary is a coboundary. Therefore, the cup product above induces

$$H^k(X; R) \times H^l(X; R) \xrightarrow{\smile} H^{k+l}(X; R).$$

We will use the cup product to understand 4-manifolds.

#### 5. 4-MANIFOLDS

**Definition 5.1.** The symmetric bilinear form

$$Q_X : H^2(X, \partial X; \mathbb{Z}) \times H^2(X, \partial X; \mathbb{Z}) \rightarrow \mathbb{Z}$$

defined by  $Q_X(a, b) = \langle a \smile b, [X] \rangle = a \cdot b \in \mathbb{Z}$  is called the intersection form of  $X$ .

When  $X$  is oriented, it admits a fundamental class  $[X] \in H_4(X, \partial X; \mathbb{Z})$ . The cup product  $a \smile b : H_4(X, \partial X; \mathbb{Z}) \rightarrow \mathbb{Z}$  thus can be applied to  $[X]$ , so this definition makes sense. The intersection form is bilinear because the cup product is bilinear.

The importance of the intersection form comes from the observation that  $Q_X(a, b)$  can be interpreted as the intersection number of certain submanifolds in  $X$ .
